

Security incident report

Section 1: Identify the network protocol involved in the incident

HTTP port 80 as this is used for connecting to web servers.

Section 2: Document the incident

The source computer sends a connection request, the reply connection is acknowledged, then GET appears, suggesting it could be the malicious file. Traffic is then routed from the source computer to another DNS server, a different website with a new IP address, the traffic is now between this website and the source computer. The port number changed on the source computer when redirected to a new website.

Section 3: Recommend one remediation for brute force attacks

The main reason behind brute force attacks is the use of weak, guessable passwords that gives the attacker an easy attempt into breaking into systems as most people use default and simple passwords. To mediate this, use MFA and 2FA as the user has to authenticate in another way before being granted access, this would mean the attacker can no longer do brute force attacks without the user being notified of unauthorized access.
